Product description

The SYLM3xxA series of high-voltage general-purpose operational amplifiers from Semiment is manufactured using advanced processes with full-process standardization and control. The series includes single op-amp (SYLM321A), dual op-amp (SYLM358A), and quad op-amp (SYLM324A), which feature unique circuit design techniques and classic rail-to-rail input swing. They exhibit high consistency and symmetry within the entire working voltage and temperature range, making them particularly suitable for applications that have high cost requirements and limited space, where the amplifiers can be well-coordinated and balanced with the overall circuit design.

The SYLM3xxA series includes built-in overload protection circuits that allow the amplifiers to recover from overloads and resume operation in a short amount of time, greatly enhancing the circuit's reliability.

These operational amplifiers are available in industry-standard packages such as SOP, MSOP, SOT-23, and TSSOP.

General Description

These devices contain four independent high gain frequency compensation op amps designed for single supply over a wide voltage range. Dual-supply operation is also possible if the voltage difference between the two supplies is between 3V and 36V and VCC is at least 1.5V higher than the positive value of the input common-mode voltage. The low supply current drain is independent of the magnitude of the supply voltage.

Applications include sensor amplifiers, DC amplifiers, and all traditional op amp circuits, which can now be more easily implemented in single-supply voltage systems.

Detailed Description

Input common mode

The valid common-mode range is from device ground to $VCC - 1.5V$ ($VCC - 2V$ over temperature). The input may exceed VCC up to the maximum VCC without damaging the device. At least one input must be within a valid input common-mode range for the output to have the correct phase. If both inputs are outside the valid range, the output phase is undefined. If either input is below $-0.3V$, the input current should be limited to 1mA and the output phase should be undefined.

Slew rate

Slew rate is the rate at which the op amp can change the output when the input changes. Slew rates are better for different occasions, sometimes bigger is better, sometimes smaller is better, SYLM3xxA series, these devices have a slew rate of $1.0 V/\mu s$.

Bandwidth

The gain-bandwidth product is equal to the measured amplifier bandwidth multiplied by the gain corresponding to the measured bandwidth. For op amps, the increase in bandwidth means an increase in speed, but at the same time it brings a large amount of power consumption, for general occasions, the bandwidth around 1Mhz can take into account the balance of all aspects of the op amp parameters, these devices have a high gain bandwidth of 1.0MHz.

Low input offset voltage

The SYLM3xxA family features a low input offset voltage as low as 0.35mV typical from a high voltage supply because the input offset voltage is amplified by noise gain, creating offset errors at the output. For a high-voltage general-purpose op amp, the application scenarios and scope of the op amp are maximized while minimizing the design of the low offset voltage while taking into account other op amp parameters. It is especially suitable for some occasions with high sensitivity

Typical Applications

Signal conditioning

Op amps are suitable for a variety of signal conditioning applications. The input can be powered before V_S , allowing flexibility in multiple supply circuits.

Inverting amplifier

The amplifier accepts a positive voltage at the input and then changes the voltage to a negative voltage of the same magnitude. It also turns the negative input voltage into positive in the same way.
